Name:- VALLE RAMESH

Recall:-

1. Cancer Detection:-

We need high Recall because the goal is to identify as many actual cancer patients as possible. If Recall is low, some cancer patients may be predicted as healthy (**False Negatives**) and may miss necessary treatment.

2. Heart Disease Detection:-

We need high Recall to identify as many patients with actual heart disease as possible. If Recall is low, patients with heart disease may be incorrectly classified as healthy, delaying medical attention.

3. Fire Detection:-

We need high Recall because every actual fire should ideally be detected. If Recall is low, a real fire may be classified as "no fire," which can delay emergency response.

4. Stock Market Crash Prediction:-

We need high Recall to detect as many actual market crashes as possible. If Recall is low, an actual crash may be predicted as "no crash," potentially resulting in significant financial losses.

5. Fraud Detection:-

We need high Recall to identify as many fraudulent transactions as possible. If Recall is low, some fraudulent transactions will be classified as legitimate and may go undetected.

6. Disease Screening:-

We need high Recall to identify as many people with the disease as possible. If Recall is low, infected people may be classified as healthy and may not receive appropriate treatment or precautions.

7. Defective Product Detection:-

We need high Recall to detect as many defective products as possible. If Recall is low, defective products may be classified as good and reach customers.

8. Cyberattack Detection:-

We need high Recall to detect as many actual cyberattacks as possible. If Recall is low, some attacks may go undetected, potentially causing security or data loss.

9. Missing-Person Identification:-

We need high Recall to identify as many actual matches as possible. If Recall is low, a genuine match may be missed, reducing the chance of identifying the missing person.

10. Emergency Detection:-

We need high Recall to detect as many genuine emergency situations as possible. If Recall is low, a real emergency may be classified as a normal situation, which could delay the response.

Precision:-

1. Spam Email Detection:-

We need high Precision because emails predicted as spam should actually be spam. If Precision is low, legitimate emails may be incorrectly classified as spam (**False Positives**) and important messages may be missed.

2. Security Alerts:-

We need high Precision so that security alerts are generated mainly for genuine threats. If Precision is low, many harmless activities may be flagged as threats, creating unnecessary alerts.

3. Medical Treatment Recommendation:-

We need high Precision when a positive prediction leads to a medical treatment or intervention. If Precision is low, healthy patients may be incorrectly identified as needing treatment.

4. Expensive Marketing Campaign:-

We need high Precision when targeting customers for an expensive campaign. If Precision is low, many customers who are unlikely to respond may be targeted, wasting marketing resources.

5. Search Engine Results:-

We need high Precision so that the results shown as relevant are actually relevant to the user's search. If Precision is low, users will receive many irrelevant results.

6. Product Recommendation:-

We need high Precision so that recommended products are genuinely relevant to the customer. If Precision is low, customers may receive many irrelevant recommendations.

7. Fraud Alerts:-

We need high Precision so that transactions flagged as fraudulent are actually likely to be fraudulent. If Precision is low, many legitimate transactions may be incorrectly flagged, causing inconvenience to customers.

8. Credit Card Transaction Blocking:-

We need high Precision before automatically blocking a transaction as fraudulent. If Precision is low, genuine purchases may be blocked, frustrating customers.

9. Job Candidate Screening:-

We need high Precision when candidates predicted as suitable are forwarded for further selection. If Precision is low, many unsuitable candidates may be shortlisted, wasting recruiters' time.

10. Content Moderation:-

We need high Precision when automatically flagging content as harmful or violating rules. If Precision is low, legitimate content may be incorrectly removed or restricted.
